

Water Potential

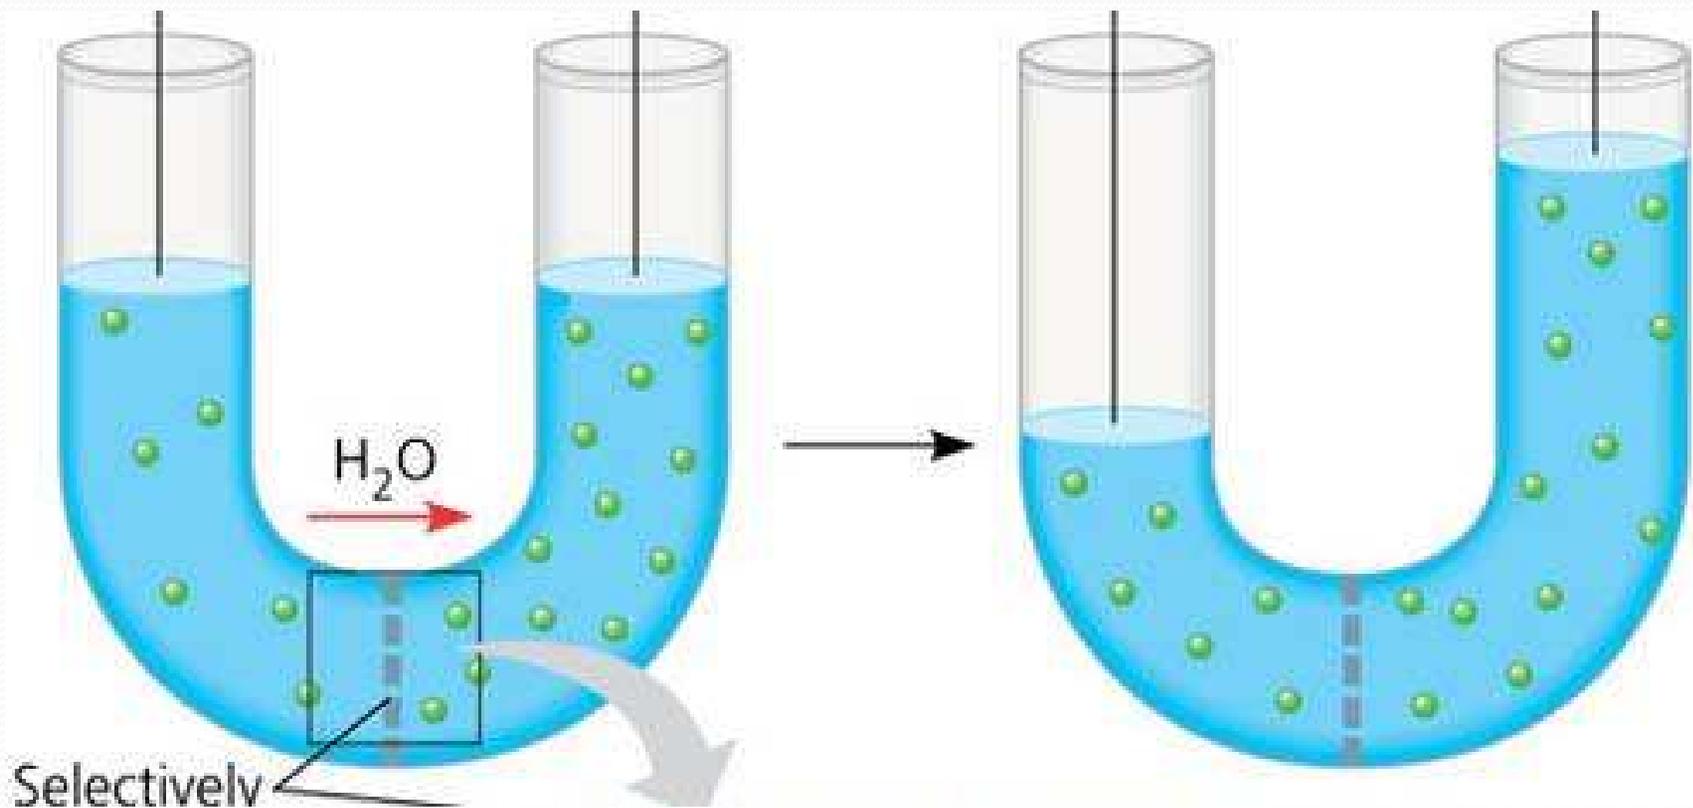

And some other osmosis related stuff

So far, what have we observed?

Osmosis

- Water diffuses from areas of high water concentration to areas of low water concentration
- How can we explain this?

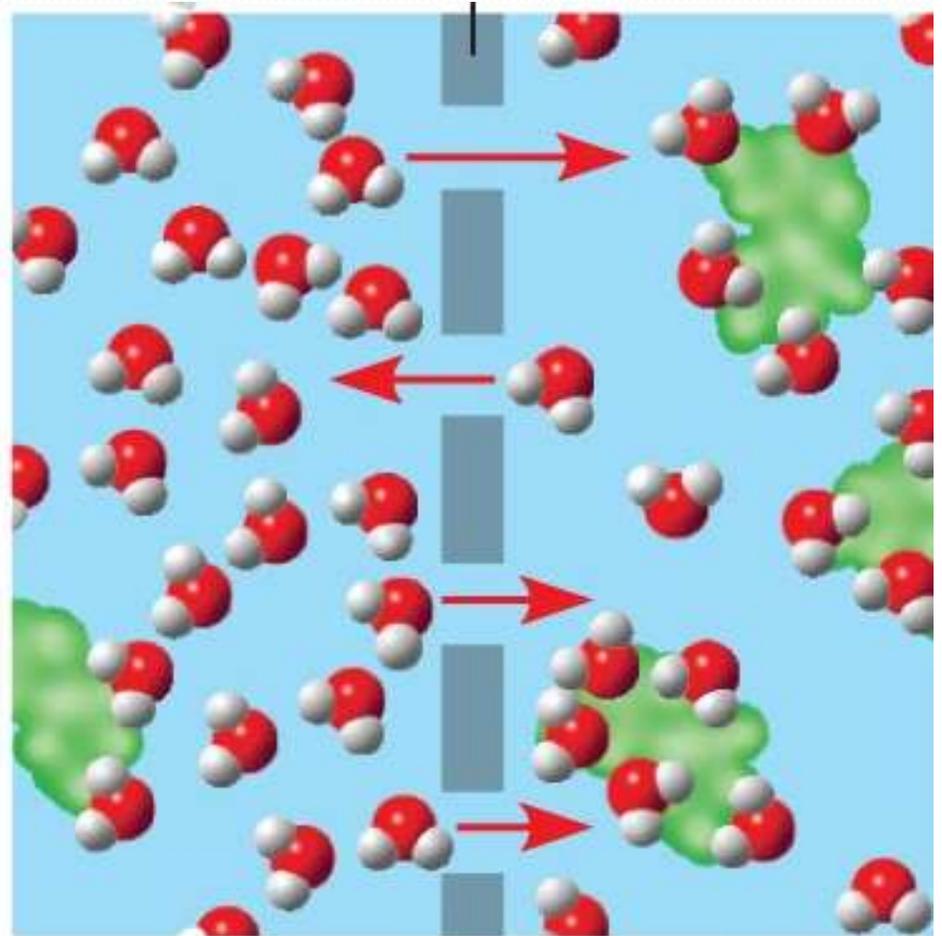

Another way to think about it.

- Water moves from areas of low solute to high solute
- Logic says that having a higher concentration of solute, means also having a lower concentration of water and naturally water will flow into the area of lower water concentration.
- True, but what is the rest of the story?

Free water!

- Some water becomes unavailable to cross because it is attracted to a hydrophilic solute
- BUT, water will still move from the region of lower solute concentration to the region of higher solute concentration until the solute concentrations are equal

Dialysis tubing and tonicity

- What is able to move across the tubing?

How does osmosis affect cells?

- Animal cells?
- Plant cells?

What is water potential?

- Water potential predicts which way water diffuses through plant tissues.
- Abbreviated by the Greek letter psi (Ψ)

What is water potential?

- Potential energy of water
 - Free energy per mole of water
 - Mole: molecular weight of a substance
 - It takes pressure into account, along with solute concentration

- Where does the pressure come from?

The Equation

- $\Psi = \Psi_p + \Psi_s$

- Ψ_p is pressure potential

- Ψ_s is solute potential

- Water potential = Pressure potential + Solute Potential

The Equation

- $\Psi = \Psi_P + \Psi_S$

- Ψ_P : the physical pressure put on a solution.
 - Can be positive or negative.
- Ψ_S : proportional to the amount of dissolved solute in the solution. (Also called osmotic potential).
 - Always negative because it decreases the ability of water to move.

Water potential determines the direction of movement of water

- $\Psi = \Psi_P + \Psi_S$

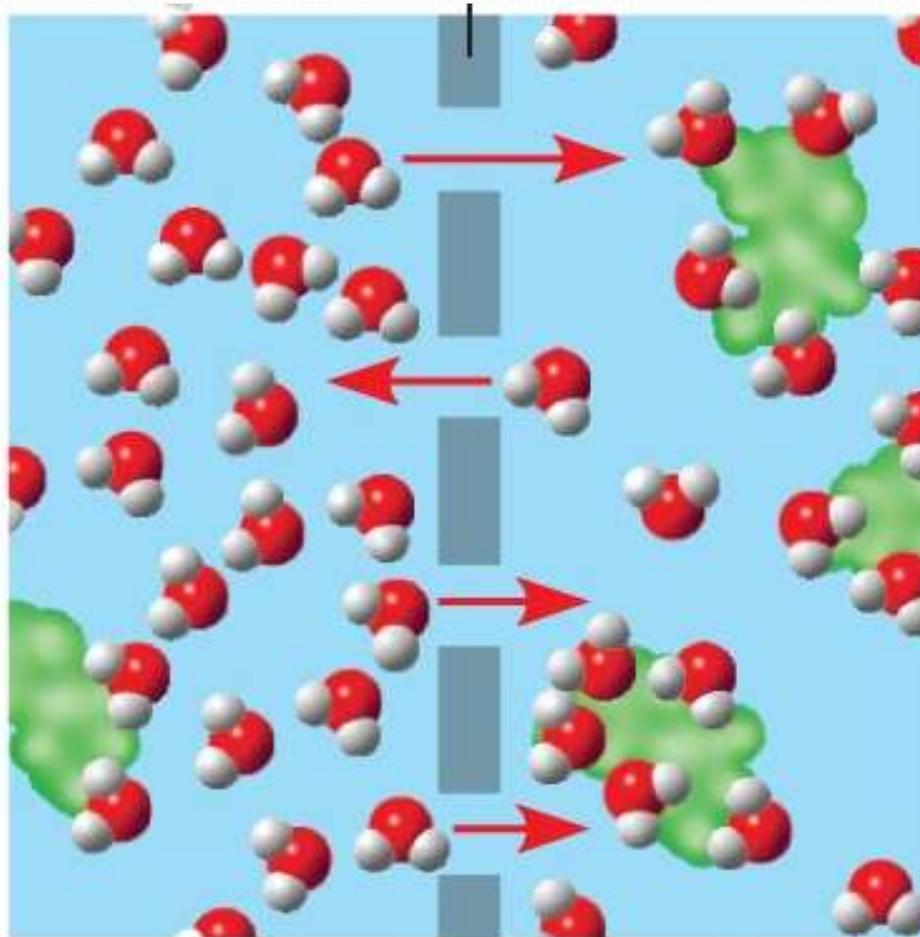

- This means that water will move from areas of high water potential to areas of low water potential.
- High water potential is more positive
- Measured in Mpa (Megapascals, a unit of pressure)

How do you get a negative pressure potential?

How do solutes decrease the ability of water to do work?

Free water!

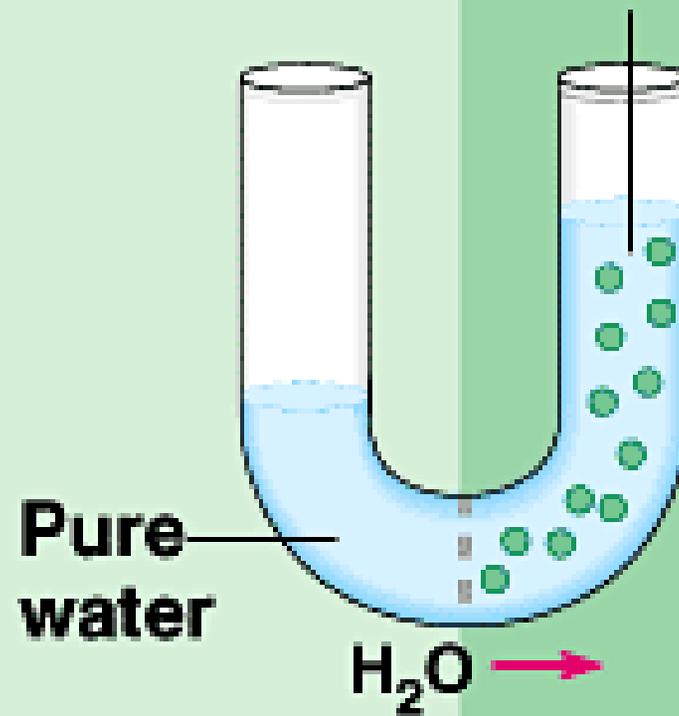

How can we explain water
movement in an artificial system?

(a)

0.1 M
solution

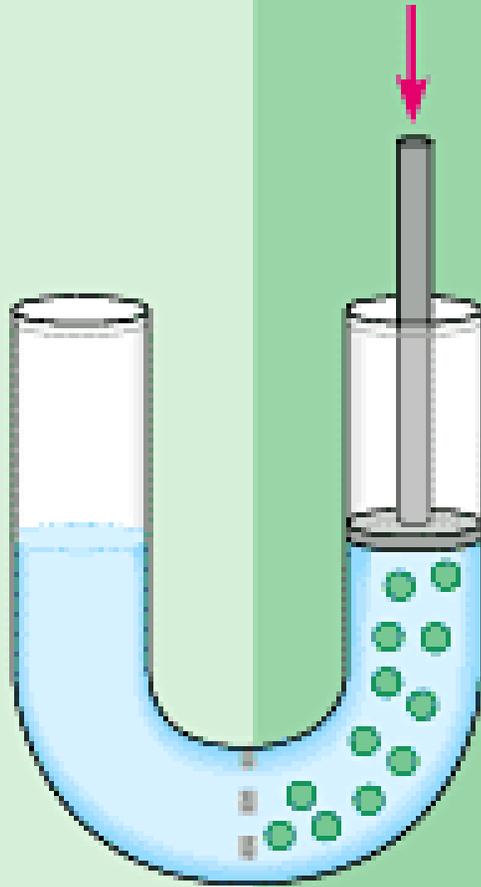

$$\psi = 0 \text{ MPa}$$

$$\psi_P = 0$$

$$\psi_S = -0.23$$

$$\psi = -0.23 \text{ MPa}$$

(b)

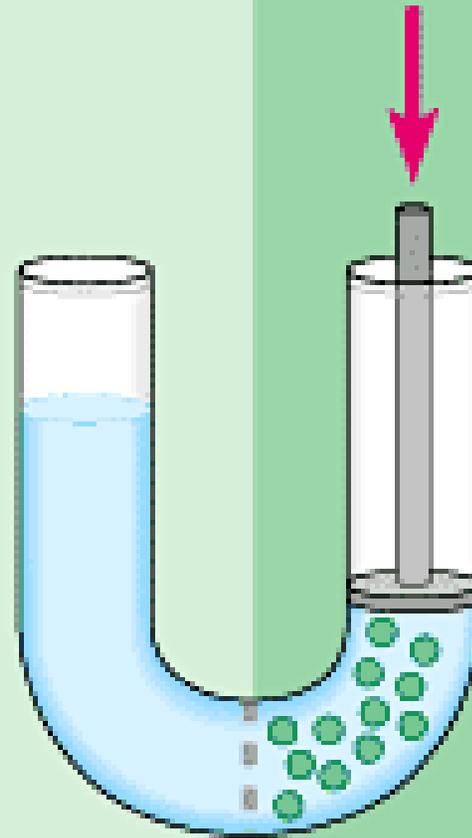

$$\psi = 0 \text{ MPa}$$

$$\psi_p = 0.23$$

$$\psi_s = -0.23$$

$$\psi = 0 \text{ MPa}$$

(c)

H_2O

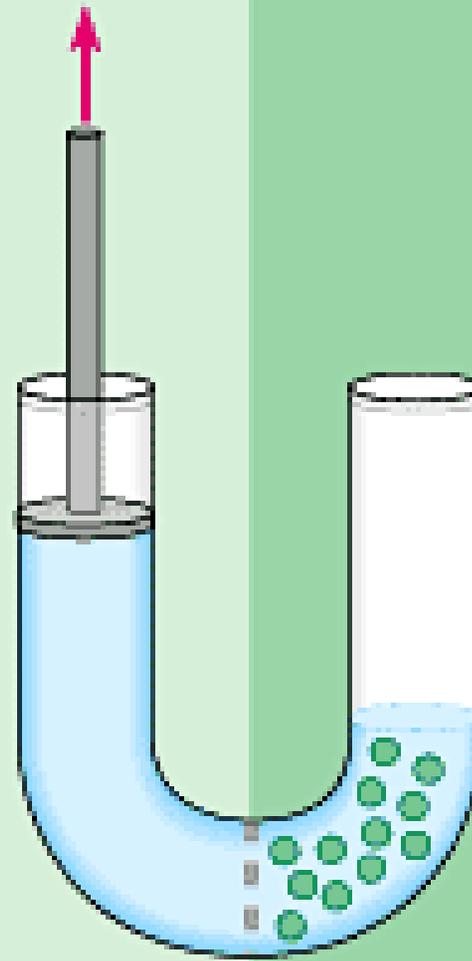

$$\psi_p = 0.30$$

$$\psi_s = -0.23$$

$$\psi = 0.07 \text{ MPa}$$

$$\psi = 0 \text{ MPa}$$

(d)

$$\psi_p = -0.30$$

$$\psi_s = 0$$

$$\psi = -0.30 \text{ MPa}$$

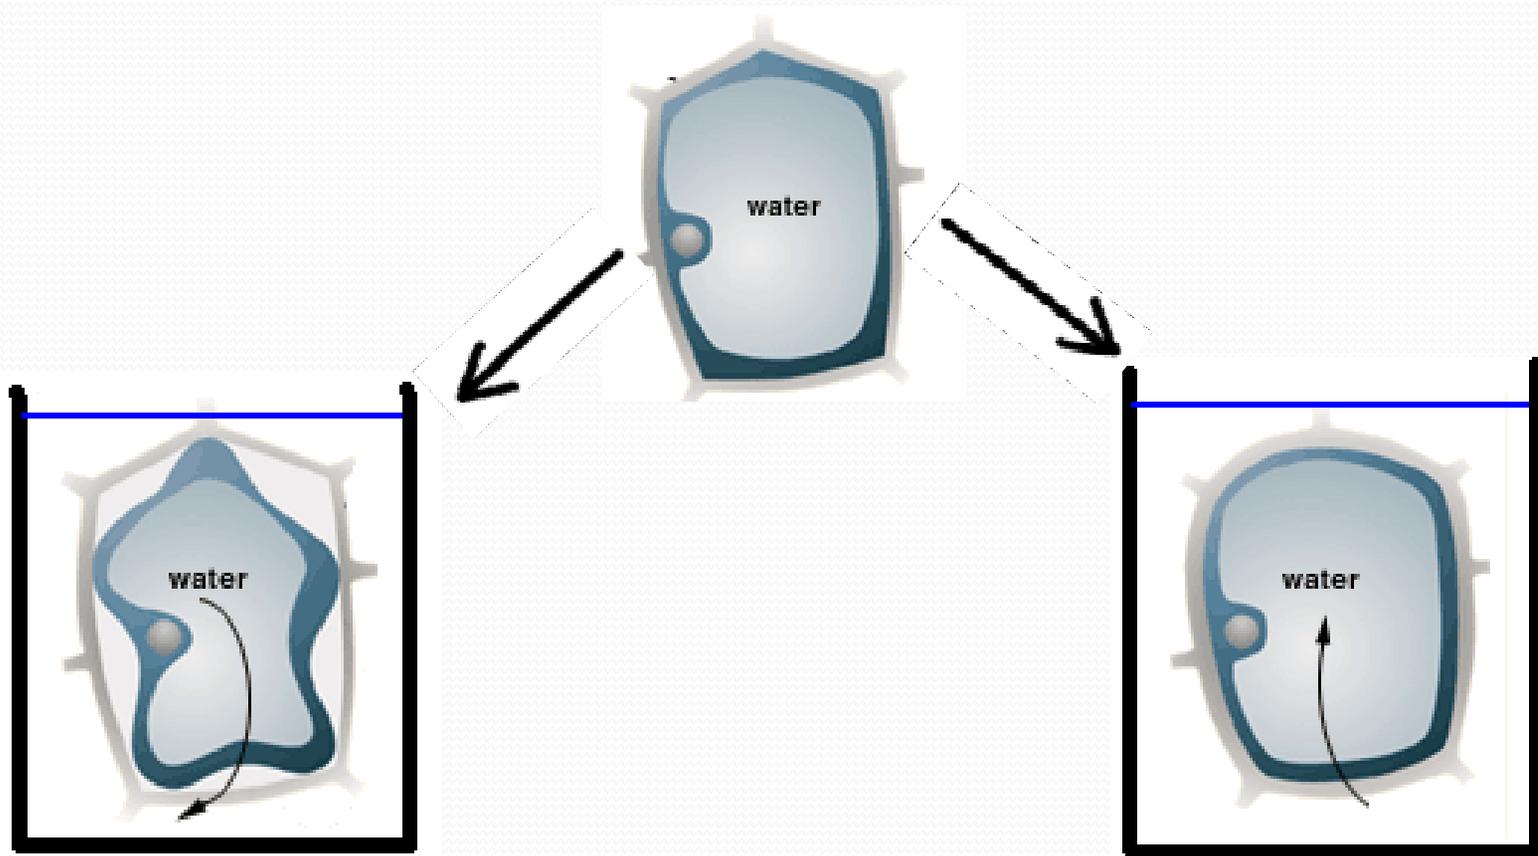

$$\psi_p = 0$$

$$\psi_s = -0.23$$

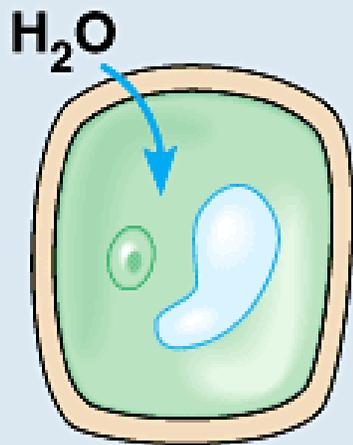

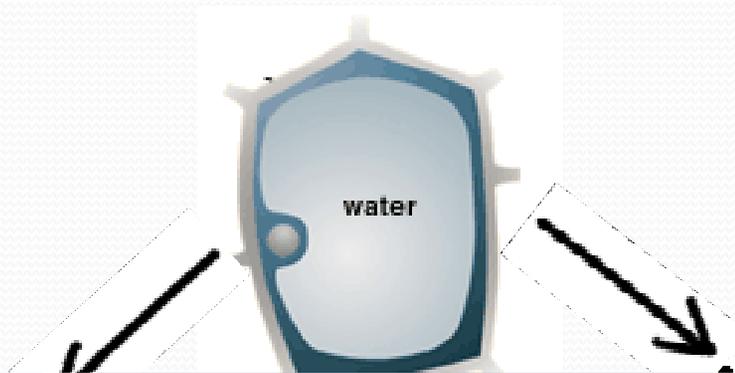

$$\psi = -0.23 \text{ MPa}$$

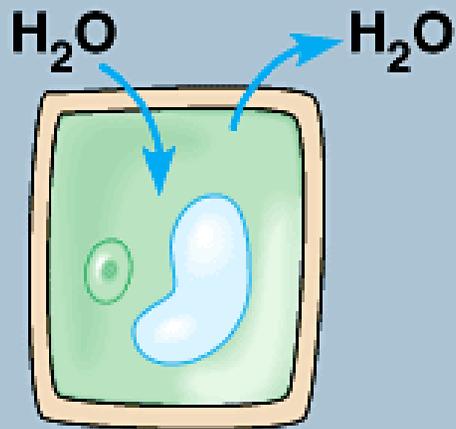

How does water potential affect living plant cells?

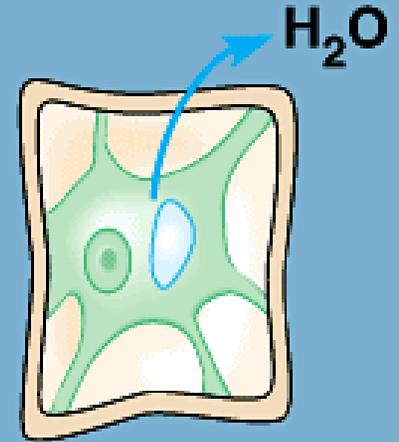

What do we call the results on these cells?

Turgid (normal)

Flaccid

Plasmolyzed

How does turgor play a part in this?

- As the cell swells, the plasma membrane pushes on the cell wall.
- The wall pushes back
- Eventually equilibrium is reached as Ψ_p is added

- What do you think happens to water movement at this point?
- Demonstrate how this can occur using the equation

What's the point of all this?

- We can predict the direction that water will flow
- Remember, water will move from areas of high water potential to areas of low water potential

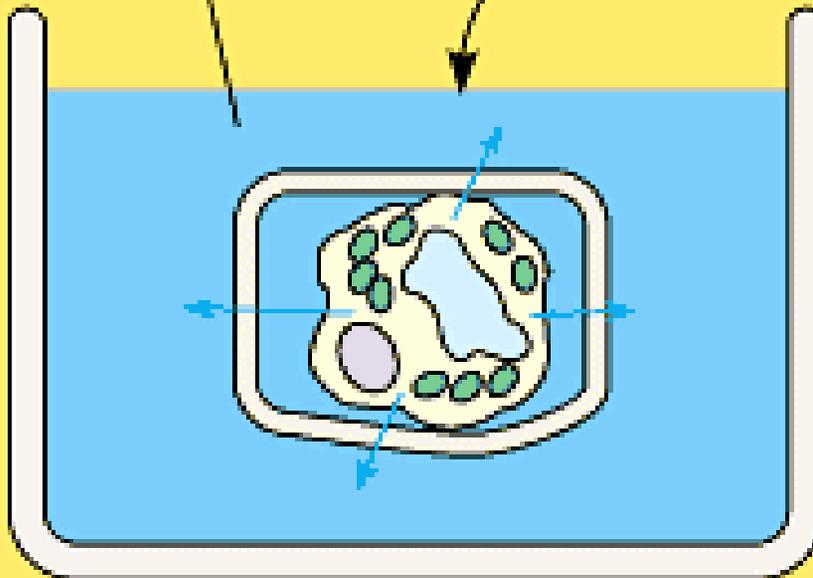

0.4 M sucrose solution:

$$\begin{array}{r} \psi_p = 0 \\ \psi_s = -0.9 \\ \hline \psi = -0.9 \text{ MPa} \end{array}$$

Flaccid cell:

$$\begin{array}{r} \psi_p = 0 \\ \psi_s = -0.7 \\ \hline \psi = -0.7 \text{ MPa} \end{array}$$

Cell after plasmolysis:

$$\begin{array}{r} \psi_p = 0 \\ \psi_s = -0.9 \\ \hline \psi = -0.9 \text{ MPa} \end{array}$$

(a) Initial conditions: cellular $\psi >$ environmental ψ

Distilled water:

$$\psi_p = 0$$

$$\psi_s = 0$$

$$\psi = 0 \text{ MPa}$$

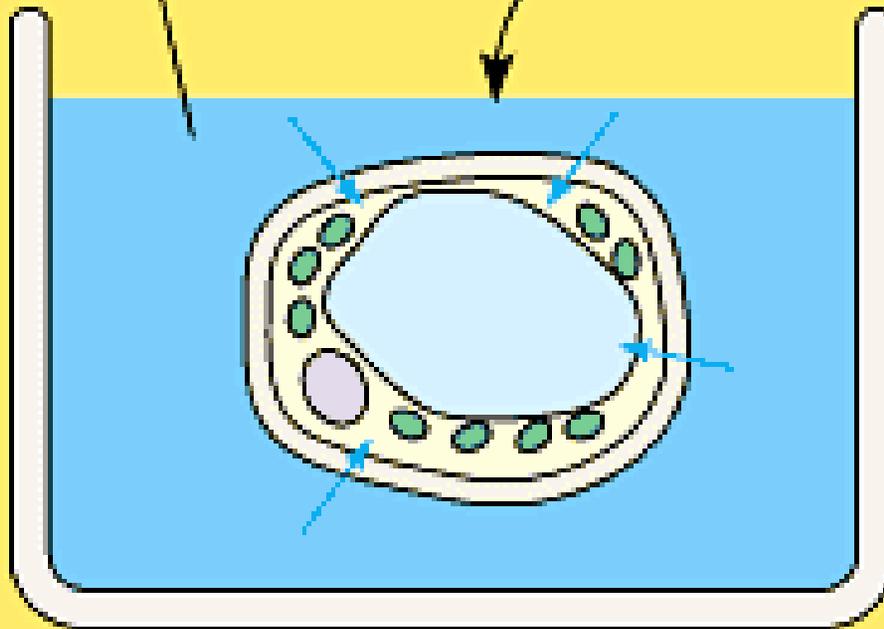

Flaccid cell:

$$\psi_p = 0$$

$$\psi_s = -0.7$$

$$\psi = -0.7 \text{ MPa}$$

Turgid cell at osmotic equilibrium with surroundings:

$$\psi_p = 0.7$$

$$\psi_s = -0.7$$

$$\psi = 0 \text{ MPa}$$

(b) Initial conditions: cellular $\psi <$ environmental ψ

Benjamin
Cummings

Calculating the solute potential

- Page S 52
- **$\Psi_s = -iCRT$**
- i = Ionization constant (1.0 for sucrose)(What is ionization?)
- C = Molar concentration
- R = Pressure constant (0.0831 liter bars/mole K)
- T = Temperature in K ($K = 273 + ^\circ C$)

Practice

- Calculate the solute potential of a 0.1 M sucrose solution at 25 °C.
- If the concentration of sucrose inside of a plant cell is 0.15 M, which way will the water diffuse if the cell is placed into this solution?
- What must the turgor pressure equal if there is no net diffusion?

Practice

- Calculate the solute potential of a 0.1 M NaCl solution at 25 °C.
- If the concentration of NaCl inside of a plant cell is 0.15 M, which way will the water diffuse if the cell is placed into this solution?
- What must the turgor pressure equal if there is no net diffusion?

What do we do with Ψ_s ?

Ok, now let's answer the questions

- Page S59
- How can you measure the plant pieces to determine the rate of osmosis?
- How can you calculate the water potential of the cells?
